ABSTRACT
We present the design and evaluation of MyPosition, a public display in the form of a large projection, featuring an interactive poll visualization. MyPosition aims at facilitating the deliberation and comparison of individual opinions on locally relevant topics in an opportunistic and engaging way. We evaluated MyPosition in an in-the-wild study and demonstrated that the engaging nature of the installation was effective in enticing public discussion. We found that (i) the increased identifiability of users positively impacted the engagement with and the social debate around the installation, however lowered the actual voting rate; (ii) people submitted their personal opinion instead of playing around with the interactive features; and (iii) the display led to considerable discussion as well as nudging among people, in particular in zones beyond the interaction area in front of the screen.

Public display; urban screen; urban visualization; in-the-wild study; awareness, reflection; gestural interaction.

ACM Classification Keywords
H5.m. Information interfaces and presentation (e.g., HCI): Miscellaneous.

INTRODUCTION
Interactive electronic displays are becoming increasingly ubiquitous in public space, showing up in bus stops, community centers, or museums. As situated media technology is rapidly maturing, it is likely that the trend will accelerate, so that people will become more accustomed to it [15]. Although the majority of currently existing urban displays serve mainly commercial, artistic or entertainment purposes, they might offer a promising communication platform for citizens [5, 9, 34], such as for increasing public discussion on socially and locally relevant topics [1, 31].

The identification and recognition of local concerns and views forms an essential aspect of encouraging civic engagement, allowing the deliberation of public opinion and the discussion of alternative perspectives [35]. Several initiatives have already addressed the idea of creating new, agile platforms of communication by embracing the potential of online technology [26]. For instance, it has been shown that community networks [32] are able to support local engagement and collaboration on civic topics [24, 29]. However, these platforms are often not easily accessible (i.e. people need to remember ways of accessing these tools, provided they have ways to access the Internet) or opportunistic (i.e. people need to dedicate time and effort). Furthermore, they tend not to be well situated, as they present a ‘local’ concern in a medium that is unrelated to the underlying social-cultural context [37]. Besides, these tools have limited ways of synchronous situated social interactivity, such as face-to-face encounters and discussion.

We propose to address issues of polling local opinions by combining the opportunistic and situated accessibility of interactive public displays with the qualities of a social visualization. By its original definition, social visualization describes the enriching of social (electronic) communication by making its salient qualities visible in easily accessible and understandable ways [8]. Research in this field has indicated that people seem to become encouraged to use social visualization for participative purposes, and potentially organize social activities alongside [7, 12]. While social visualization has mainly focused on graphical depictions of online and social media activities, little is known on whether it can be successfully deployed in other contexts or presentation media.

For instance, there are early indications that the public visualization of private data may incite physically situated discussions and debate by viewers, as the public externalization of private data can trigger feelings of friendly competition, social comparison, or social pressure [36]. Inspired by previous findings on situated polling for increased opinion deliberation on a given local topic [35], we thus focus on enticing situated discussions and reflections by way of moving online-style, non-scientific polls to the public realm, and explicitly visualizing the resulting statistics.
We contribute by (1) introducing the design of an interactive poll visualization of opinions originating from passer-bys, and based on gesture-based interaction; (2) proposing different degrees of identifiability of the visualized opinions; (3) evaluating MyPosition in-the-wild; and (4) discussing the implications for design and use of public interactive visualizations as tools for increasing civic discourse. Our study demonstrated that the engaging nature of the installation was effective in enticing public deliberation and discussion. The main findings that emerged from the study are: (i) increased identifiability of the visualized votes increased the motivation to engage with the installation and forged open social discussion in the social space around the display, however less people actually submitted a vote; (ii) visitors expressed and submitted their personal opinion instead of playing around with the interactive features of the installation; (iii) the display led to significant discussion as well as nudging, in particular outside the direct interaction area.

RELATED WORK
Several in-the-wild studies of public displays have been presented, ranging from museums [17] to urban settings [23]. Such public displays are generally designed to communicate information of relevance to a specific group of people [13], support opportunistic conversations [19], provide playful information experience [17], or enrich casual interactions of people sharing a physical environment [21]. Few public displays have been specifically designed for a civic purpose, such as to increase awareness, discussion and reflection on local topics. We compare MyPosition to existing work regarding SMS-based civic communication displays, playful interfaces for civic discussion, and public voting systems.

SMS-based Civic Communication Displays
Some public displays create an open forum for public expression by providing a communication channel to citizens via SMS messaging, for instance TexTales [1] or Discussions in Space [31]. TexTales presents civic topics, such as “smoking in public places”, whereas Discussions in Space is specifically focused on enticing civic interaction within the context of urban planning proposals. Results from these projects indicated that conversations might be sustained not only within the system, but also carried on in the physical and social space around it. We were inspired by this observation and aim to provide a more detailed analysis of the actual in-situ engagement of individuals and groups with the installation and its underlying topic. We also explore more immediate and playful interaction based on computer vision, thereby avoiding the moderation requirement of the SMS input modality and the associated feedback delay.

Playful Interfaces for Civic Engagement
Some digital urban installations aim to encourage more playful or reflective civic engagement on socially relevant topics, exploring the experiential and reflective potential of the interactive system [2]. For instance, CO2nession constitutes of a video-booth-like installation, where citizens are invited to enter and ‘confess their sins’ related to their CO₂ usage, which are then broadcasted on urban displays distributed across the city [20]. The system capitalized on the increased potential for reflexivity with regards to personal and civic values. In MyPosition, we explore a more in-situ communication between citizens, hoping to encourage active engagement with others’ opinions and stimulate public discussion. Similar to MyPosition, Climate on the Wall was conceptualized to encourage passers-by to communicate their opinion (on climate change), by forming statements with their bodily movements along a projection wall [11]. A field trial showed that the playful nature of interaction was actually a hindrance for a meaningful participation, as many participants rather played with the interaction and few meaningful sentences were formed [11]. With MyPosition, we aimed at finding a good balance between playful interaction and meaningful participation.

Public Voting Systems
Several research projects already used voting mechanisms in a social context such as bars [25] and classrooms [3] in order to encourage public opinion deliberation. MyPosition extends this work towards a more civic focus and a systematic in-the-wild evaluation with a larger group of people. Recently, Taylor et al. [35] presented results of a long-term deployment of a voting device within three highly frequented public locations, allowing residents to express in-situ a yes/no opinion on a locally relevant topic [35]. Viewpoint aimed to increase community members’ individual perception of their own efficacy. MyPosition builds on this work, while trying to promote awareness and on-site social debate among participants. MyPosition is also designed for rapid, opportunistic responses, yet allows for a wider range of sentiments to be submitted. Furthermore, MyPosition is a social visualization, in that individual opinions are still readily recognizable and identifiable, and utilizes more playful and engaging interaction.

DESIGN PROCESS
MyPosition was developed through an iterative design process involving the production of successive designs, the evaluation of low-fidelity sketches, mockups, working prototypes, and preliminary in-the-wild tests.

Design Goals
We set out to develop an urban poll visualization that would entail several design goals: a) provide awareness on individual contributions submitted by passer-bys; b) motivate participation through engaging and playful design; c) provide a low-barrier entry for participation while minimizing misuse or accidental submissions of votes; d) explore anonymity in participation by exploring different degrees of identifiability of the individual contributions; and e) encourage opportunistic and spontaneous conversations.

THE PUBLIC POLL VISUALIZATION “MYPOSITION”
We used the Design Space Explorer Framework for Media Façades [6] to structure its design goals in regards to its location and situation, form and material, participation and visualization design.

Location and Situation
A public situation determines the shared understanding and social interpretation of cues present in the physical
environment [16]. Therefore, we specifically aimed at locating MyPosition within an environmental context that naturally hosts informal, opportunistic social activities and encourages different forms of informal gathering, dwelling and transition (design goal e), such as spaces in front of local cafés or shops, or entrance halls of cultural or community centers.

**Physical Form and Material**
MyPosition was implemented using a large rear projection canvas measuring 5x2 meters, two short-throw projectors and two Kinect cameras. All technical devices can be placed behind the screen to provide a compact setup that could be seamlessly and securely integrated in the physical environment. The interaction zone, i.e. the floor area in front of the screen in which users can be detected, measures about 5x3 meters.

**Participation**
MyPosition allows any passer-by to express her opinion on a given topic (design goal a) by way of a full-body interaction method. We specifically chose this type of interacting in order to: i) create a more enjoyable experience when participating (design goal b) in an otherwise relatively serious context [11], ii) support a more lightweight, inadvertent way of interaction [23] (design goal c), and iii) allow multiple participants to simultaneously interact with our system (design goal c).

A person is able to vote by consciously positioning herself along the display in front of a desired opinion section along a 4-point scale: ‘strongly disagree’- ‘disagree’-‘agree’-’strongly agree’. In order to place a vote, the participant has to raise her hand. This gesture was preferred as it is commonly used to visibly express opinions in public spaces such as town halls, podium discussions, or classrooms. To avoid accidental submissions, we introduced a dwell-time, for which the gesture has to be performed. By ‘forcing’ the potential voter to perform an explicit gesture, this ‘submission’ mechanism also aims to minimize possible misuse such as flippant [35] or merely playful interaction [11]. (e.g. design goal c) This act of public ‘submitting a personal opinion’ was also meant to enhance public engagement by providing an opportunistic moment at which other passes-by could observe and discuss the action taking place (design goal e).

**Visualization Design**
We chose a visualization style that combined the “seriousness” of the topic with a more accessible and enjoyable way of representing the voting statistics. The visualization consists of a set of square tiles, of which each corresponds to an individual opinion submitted by a passer-by (Fig. 1.D). Each of the preference options is represented by a different color and a textual label, and occupies an equally large horizontal section of the screen (Fig. 1.B). The voting topic is shown on the top (Fig. 1.A).

**Animations**
We implemented several dynamic visual features, to make the visualization richer, vivid, and more understandable. For instance, tiles that are in the direct proximity of a visitor who is passing through the interaction zone enlarge in a smoothly animated way to attract her attention. Once this person moves closer to the projection, her relative position – and thus her implied opinion (see subsection Participation) – becomes previewed as an animated ‘polaroid’-like visual form, rendered over the existing visualization (Fig. 1.C and Fig. 2). An animated textual hint explains how to place a submission: “Raise your hand to agree” (Fig. 2.A), as an efficient, integrated visual ‘hint’ to inform users on how to perform a gesture in a public display setting [38] (design goal c). Once a participant starts to correctly perform the voting gesture, a clock-wise animation gradually colors her preview, thus providing real-time progress feedback on the dwell-time (Fig. 2.B). Upon registering a vote, the screen shortly flashes to visually acknowledge the submission. The newly created tile then gets added to the collection of tiles that were already submitted.

**Representation of Opinions**
In order to explore the relationship between (pseudo-) anonymity and participation in the poll (design goal d), we created three different representations of an individual opinion, each representing a different degree of identifiability: color, contour, and image.

- In color mode (low identifiability) all tiles look identical, making it impossible to identify which vote was submitted by whom (see Fig. 1-Top).
Figure 2: Close-up of the preview of a currently interacting participant in the three representation modes (color, contour, image); (A) The integrated hint for performing the gesture; (B) the clock-wise visualization of the gesture dwell-time.

- In contour mode each tile contain a graphical contour of the person who placed the vote, as captured by the camera. While it is difficult to identify other participants, a participant might be able to recognize her own submission (see Fig. 1-Middle).

- In image mode (high identifiability) each tile contains a photo of the corresponding participant, making it possible to identify who submitted what preference in the visualization (Fig. 1-Bottom).

PRELIMINARY FEEDBACK

In order to identify potential usability flaws, we evaluated MyPosition in an expert study consisting of three HCI researchers. The two most significant results included extending the dwell-time of the voting gesture (2s) and adding an explicit representation of the dwell-time progress (Fig. 2.B). We also collected informal feedback from five non-experts, in particular on the social aspects of the voting gesture. We did not discover any concerns about performing it in a public setting.

PILOT FIELD STUDY

MyPosition was installed for five consecutive days in the district of Wedding (Berlin, Germany), where it was accessible to passers-by and visitors via a large rear projection on the glass pane of a window of a local cultural event center (Fig. 3). We took notes on people’s behavior towards the installation (e.g. attention and reactions) for 3 to 4 hours every afternoon (from 4pm to 10pm). Additionally we conducted interviews with random participants during an international freelance event hosted in a semi-public indoor lounge of the same center. After discussion with the organizers, we chose “I think that freelancing is a good way to make a living” as a voting topic. The interview questions dealt with the general attitude towards the installation and the submission and visualization of votes in a public setting. In total, we talked to 6 people (4 male, 35-50 years), all self-employed professionals.

Findings

While approximately a majority (70%) of all outdoor passers-by were attracted by the inadvertent visual feedback produced by their movements, only few stopped and had a closer look. The unpleasant weather conditions (i.e. below-freezing temperature and snowy conditions) hampered the overall motivation to stay, as well as the establishment of idling, exploration and discussion zones in the vicinity of the installation. In contrast, the indoor placement of MyPosition did not facilitate any inadvertent interactions, as events took place in an area spatially detached from the installation’s vicinity, so people’s paths upon entering the space did not pass by. However, the setting and in particular the social laid-back nature of the event provided situations of idling and contemplation around MyPosition after the end of the event. Participants who approached, considered the installation generally quite understandable and appealing. Interviewees suggested various possible venues and application areas for further integration, such as for education, general referenda, or local community issues. Several participants criticized the visualized topic as being too general for the people at the setting to engage. While people seemed comfortable with the public way of voting, we noted several concerns about the public collection and possible uncontrolled publication of private opinions, with several participants mentioning Facebook or other online platforms characterized by exposed social data.

FIELD STUDY

We deployed MyPosition over the course of one working week in the foyer of a large university cafeteria. As a topic, we chose “I think a bachelor’s degree is the best preparation for a job”. This choice was motivated by a recent and highly debatable change in the university degree system in Germany. The goal of the study was to gain insight into the following questions:

(i) What is the impact of identifiability on voting behavior and participation?

(ii) Does playfulness of the display, including the public gesturing, interfere with meaningful participation?

(iii) What are the social interactions caused by the display?

Location Description

The deployment location was mainly visited around noon by students or staff of the TU Berlin and University of the Arts, as well as locals living nearby. The contextual setting of the space was characterized by several distinct zones: two transit areas situated between the main entries/exits and the dining-hall of the cafeteria; a waiting area in front of a coffee shop, as well as several sitting areas (Fig. 7). Based on previous research [21] and our experience from the pilot studies, we situated the projection in a transit area in front of the large sitting area, to maximize potential overlapping situations for both inadvertent interactions with the installation as well as idling, contemplation and gathering in a more broader space (Fig. 7).

Observations

Two researchers observed passers-by for 4 to 6 hours throughout the evaluation period. We kept field notes such as simple sketches annotating the relative locations and movements of passers-by. We observed and listened in to visitors, capturing their initial behaviors (e.g. direction of movement, attention, and reaction) as well as their opinions during their interactions or while discussing among themselves. To facilitate the process, we devised observational categories that were subsequently refined. In
an overall period of 5 days (approx. 30 observation hours),
we took notes of about 445 random persons who noticed
the projection, 356 of which (80%) were in groups.

Semi-structured Interviews
We approached individuals and groups of people who had
interacted with MyPosition and/or spent at least 2 minutes
in front of it. The interviews lasted from 5 to 20 minutes
and were typically performed after visitors placed a vote. At
the beginning of each interview, we inquired about the
purpose and habits of visiting the location and their initial
motivation for approaching the projection. We further asked
about general voting habits, civic discussion behavior, and
attitudes towards engaging in issues related to the location.
We also noted age and gender of participants, and their
social context (e.g. whether they came alone, in group,
etc.). The interviews included questions regarding
MyPosition in terms of its understandability, its potential
usefulness, its interactivity, the representation of votes, as
well as any other suggestion or thought in relation to the
project. Overall, we conducted 17 interviews with 26
visitors (3 female). We attribute the unbalanced gender to
the higher ratio of male students at the nearby technical
university. We interviewed 9 individuals, 7 couples and one
group of 3 people. The majority of interviewees were
between 20 to 30 years old (except of 5 who were between
55 and 65 years).

System Logs and Captures
Our system continuously recorded anonymous data of
passers-by and participants, such as log files, screen video
captures and depth image streams. Besides the three-
dimensional position data of each individual that entered
the interaction zone (captured at 30 Hz), the log files
contained timestamps of all relevant user events, such as:
visitors entering or leaving the interaction zone; positioning
themselves in front of a specific voting option; or
performing the voting gesture. The screen content was
captured in full resolution at 15 frames per second (fps),
while the depth image streams of the sensors was captured
at 30 fps. Over the course of the deployment, we collected
data of about 4980 passers-by. As 80% of passers-by
occurred within the core hours (12pm-3pm), our
quantitative analysis is based on that time period.

Experiment
To quantitatively assess how the different vote
representation modes affected participation, the system
automatically switched between contour, image, and color
every 30 minutes (see Figure 1). Only votes that were
placed during the current mode were presented on the
screen. In order to minimize any effect of the order of
options on voting, after half of the deployment time we
reversed the order of the options.

Data Analysis
We analyzed our collection of field notes and visitor
opinions using grounded theory [33] to draw bottom-up
findings based on the direct quotations and to establish
hierarchies and connections among remarkable findings.
Apart of the the descriptive statistics of visitors’
participation, we used the system logs together with the
interview data to evaluate the impact of identifiability. We
further used this data to triangulate participants’ comments
and reactions upon participation.

RESULTS
General Overview of Participation
Our quantitative data analysis is based on an average of 880
(min=760, max=960, std=75) daily passers-by between
12pm-3pm. People stayed in front of the projection on
average for 4.6s (std=16.1s). Those, who placed a vote
stayed for 27.9s (std=41.9s) and those who did not for 3.9s
(std=14.2s).

Self-Reported Perception of Community Engagement
All interviewees turned out to be regular (daily- or weekly-
basis) visitors of the university restaurant. The majority of
them (77%, 21/26) were students or alumni of the
university (aged 20-35 years), the rest were adults of
varying backgrounds and professions ranging from 45 to 65
years, living close by. While 62% (16/26) claimed to
usually participate in municipal or state elections, the
majority (69%) reported to actually not engage in
community or university issues. Some of them explicitly
stated the reasons, which ranged from a lack of time, to the
fact that they could not longer participate as they were no
longer university students. In summary, the engagement
reported by visitors at the deployment location was
relatively low.
Impact of Identifiability

Did People Vote?
From the log files, we extracted the conversion rates (votes per passers-by), which we considered as a measure for the willingness of visitors to submit a vote to the system. Out of the 880 passers-by, recorded in the core hours, 217 submitted an opinion, with a conversion rate of about 5%. We observed the lowest conversion for image (3.9%), and higher conversions for contour (5.7%) and color (6.1%).

How Did People Perceive Their Increased Identifiability?
Interestingly, when asked whether they have any concerns with the vote representation, 79% (11/14) of the interviewees in image mode claimed it did not bother them at all, e.g. “[…] It does not bother me, I think it is good like that, more interesting and evocative for the people.” (P10), or “No, totally fine with me, people should see what I think!” (P21). Some even stated that their participation already implied their firm position: “Of course not, if it bothers me, I would simply not participate in the first place!” (P3). Others explained that the image representation did not affect their privacy: “Definitely I think image is a good option, actually it is relatively anonymous.” (P13).

On the contrary, around 78% (7/9) of the interviewees in the contour mode were rather skeptical towards a more recognizable vote representation in case of a “more critical” context, with a majority (67%) referring to poll domains with traditionally higher demand of security, e.g. “If it’s about elections of the parliament, I would rather stay more anonymous.“ (P8), or “Hm, if its something serious I would find it difficult to see my image displayed. It depends on the question.” (P5).

How Did People Perceive Others’ Identifiability?
Our interviewees expressed differing views regarding their opinion about being able to see the votes of others. The majority of them (62%, 16/26) found that this visualization sparked curiosity in so far they felt incentivized to participate, e.g. “Seeing others’ votes makes it more interesting for you to participate.” (P7). In particular, some seemed to find the ‘personalized’ character of the visualization appealing. For instance, P3 (image mode) explained: “[…] It’s extremely cool to see the pictures of all others. It is not just an impersonal color chart as we know from newspapers,” or (P10 – saw all modes): “The contour is playful, it shows movement and personality, it motivates people”. However, several participants expressed their doubts about the bias of one’s opinion when all others’ votes are visible, e.g. “[…] Surely the fact that you see others influences somehow.” (P5).

Did People Vote for Their Personal Opinion?
Overall, people’s voting behavior represented their actual opinion, rather than merely trying out the interactive features of the system, an problem reported in [11] and [35]. Most of the interviewed visitors (81%, 21/26) had placed a vote immediately before the interview: 91% of them were ‘against’, and 9% ‘in favor’ of the topic (similar to the logged general voting results). When asking them directly about their opinion, these participants confirmed the preference position we had noted beforehand. Seven of them even went on and specifically showed us their submissions across the options in the three representation modes. Interestingly, significantly more users in the image mode were ‘in favor’ of the statement (‘agree’ or ‘strongly agree’) compared to the contour mode ($\chi^2$=7.0, p<0.01). In addition, in the image mode, the submissions across options appeared to be more evenly distributed than in the contour mode (see Fig. 5).

Playful vs Meaningful Submission of Votes

Public Character of Voting
The act of positioning oneself along the projection in order to choose the preferred option together with the explicit voting gesture imposed a publicly recognizable aspect to
participating, which evoked curiosity and taught other passers-by how to participate. All interviewees who had placed a vote (81%, 21/26) perceived the gesture-based voting as “entertaining”, “cool”, “much funnier [as traditional voting mechanisms]” and “easy to use.” Although some visitors perceived the voting gesture as intriguing, others thought it was quite ‘exposed’. Interviewee P23 (image mode) was even more specific: “People see me all the time, if everybody is against, I would think twice about what to vote for.” One interviewee claimed this was due to the ‘openness’ of the spatial layout around the screen: “[...] Of course, the fact that you can be seen ... creates a sort of stage. [...] If it were in sort of a corridor, that people won't feel that observed.” (P9). Others related this ‘exposure’ to the time it took to place a vote: “[the visibility] is not a problem for me because it's only for a short time and does not stay” (P10), and “[...]. If [voting] were quicker; it would be more anonymous.” (P6).

**Spatial and Social Interaction Patterns**

We observed that MyPosition also created several zones of engagement within a larger area of the deployment (see Fig. 7). Outside of the active interaction zone, passers-by engaged with MyPosition in a number of other zones, such as the sitting and waiting areas in the vicinity of the projection. We also noticed that visitors congregated outside of the camera field of view, such as around the two columns located on both sides of the sitting area. These observed zones relate to the “comfort spaces” discussed in [39], which tend to give “physical and psychological comfort [...] by providing a line of sight, but giving people the feeling of being ‘out of the way’”. However, we observed that this engagement often became more active than passive contemplation, such as reading aloud, or debating and commenting in group.

**Social Learning and Social Teaching**

We noted that visitors tried out the interactive features or attempted to vote as a consequence of observing others interacting, similar to the social learning effects perceived in other public screens [27, 38]. We noticed this behavior in approximately 8% of the observed cases (35/445), which mostly unfolded around some of the comfort zones and the zone in front of the projection (see Fig. 7. A).

A more frequently observed social configuration (approximately 31% of the observed group cases, 110/356) was ‘social teaching’, where one person teaches the other(s) about the features of the installation. This situation occurred mostly among couples or groups of acquainted people. In fewer instances, mostly around the comfort zones, we observed ‘passive’ social teaching, where people explained specific features to their companions. While previous work has reported ‘teacher-apprentice’ social configurations along an interactive multi-touch wall [27], we observed social teaching happening in a larger number of engagement zones (see Fig. 7.B), often leading to participative behaviors.

**Social Discussion**

The most spatially fragmented yet most frequently observed social behavior (approximately 52% of the observed group cases, 185/356) consisted of deeper discussions about MyPosition. The majority of discussions occurred in the waiting area in front of the coffee shop (Fig. 7. C), as well as other spots within the upper transit area, where passers-by had the most optimal overview of the installation. People engaged less frequently in debate in the interaction zone in front of the projection itself, in the comfort zones, and in lower transit area close to the exit. Discussion topics included: a) the visualized voting topic and their personal preferences; b) the visualized patterns and voting results; and c) data privacy issues.

a) Voting Topic. Often discussions about the topic were triggered by more ‘implicit’ interactions by one or more members of a group. Visitors would pass through the space, notice the screen and stop for a bit observing it. They would ask each other “What do you say?” and receive response such as, “Well, obviously not [agreeing]!”

b) Visualization and Results. Over time, passers-by seemed to ‘follow’ the development of the visualization, as we noted several instances of people observing that “something has changed” [i.e. the vote representation mode, or the order of options], and discussing the possible causes of these changes, such as “privacy reasons”, or to “make it statistically correct”. The collective visualization of all submitted votes (see Fig. 1) seemed to encourage discussion about the result distribution, e.g. “Look, only five say that they totally agree,” or “There is a big contrast between the votes”.

c) Data Privacy Issues. Similar to our observations from the pilot study (see section Pilot Field Study), the image representation mode often prompted debates about the perceived privacy of the submitted votes. For instance, a girl left her group of friends, standing in the upper transit zone, to vote. Upon her coming back to the group, one of her companions said jokingly: “Now they know everything about you!”. Often privacy concerns also related to potential future publications of the data. One girl participated with her back to the projection, explaining to her friend: “I don't want to be seen on Facebook!”.

We are aware such privacy issues would be even more outspoken.
and hazardous if opinion questions are more provocative, contested or politically sensitive.

Social Nudging and Critique

Visitors often explicitly prompted their companions to vote or criticized the intentions and opinions of others. These social behaviors were noted in approximately 16% of the observed group cases (57/356). The majority of the people who nudged other visitors had already participated. These actions were often accompanied by humorous or ironic encouragements. For example, we observed two friends passing-by, one of them knew the installation already. He drew attention to MyPosition, by prompting the other one: "Look over there, that's something for you! You are so democratic, right; you always like to go voting…." Moreover, the public visibility of submitting an opinion triggered open critical attitudes towards others, which often occurred within the social context of groups. A young male prompted his friend to participate. Upon his friend saying: "I strongly agree.", the first man responds, seemingly surprised: “Are you serious!? You agree on this?”. The second one did not submit a vote. Critical attitudes were also openly expressed towards non-present participants’ preferences, reflected in the visualization: “Look over there! Somebody has agreed!”

DISCUSSION

Whereas the most valuable effect of MyPosition consisted of its ability to cause cooperative discussion, reflection and contemplation of a civic concern in a public setting, several issues should be considered when designing an interactive poll visualization placed in a physical environment.

The Identifiable Self

The identifiability of the person and her vote in the image mode did not seem to cause concerns among interviewees. However, the biggest impact was observed in the voting conversion rate dropping by 36%, which means that some people simply did not vote in this representation mode. Furthermore, votes were more evenly distributed and significantly more positive for the image mode, compared to the contour mode.

Design Implications: There may be concerns related to individual data privacy, or social factors which influence these different behaviors, especially in settings aimed at the general public, rather than a small co-located group such as in [14, 18]. Some of those people who were against the visualized statement, would not participate due to the higher identifiability of their vote in the image mode. Conversely, the situation of expressing opinion on an issue, implicitly related to the institution hosting the display (in this bachelor degree/university), would lead to a more conformist behavior, when it comes to an open criticism. Future studies could explore how the explicit choice of identifiability may influence one’s participation behavior.

The Identifiable Others

Generally, people seemed to consider the identifiability of votes on the screen stronger than the immediate publicness of the voting itself, as illustrated in the case of the girl voting with the face away from the screen (and towards the audience). In contrast, the ability to identify others was described as more “intriguing” and showing more “personality”. While we did not observe any particular attitudinal differences across the different representation modes, the public and collective depiction of people’s votes sparked considerable discussions. People compared and contrasted the visualized results, and often loudly reflected on the underlying implications, especially in cases of those votes, which were in line with the represented majority. Conversely, people would publicly criticize the opinion ‘outliers’ - e.g. the ones who have submitted a positive vote towards a statement, which is predominantly disagreed with - both the ones already depicted the visualization, as well as potential participants in the social space, they were part of.

Design Implications: This calls for attention towards the social challenges involved with the visibility of individual contributions in public visualization settings: how would people’s own contribution be effectively influenced when others’ are readily visible, is still an open question. Furthermore, while the open critical debate is a desired result, those who are less inclined to publicly submitting their personal data, might be even inhibited to express their views, when social pressure towards the ‘correct’ contribution is induced.

Naturally, our findings regarding identifiably and privacy are limited to more innocent or playful voting questions, and further studies are required to be able to extrapolate them to more sensitive, contested or controversial polls.

Playfulness vs. Meaningful Discussion

Previous research has pointed out that designing urban interactive platforms, which can both communicate meaningful information and engage, is a challenge [11]. Our field study demonstrated that MyPosition has achieved a relatively good balance between engaging, playful design and enticing meaningful discussion regarding the topic at hand. Compared to other public interventions with a civic purpose (e.g., [31] and [35]), we opted for a playful, bodily interaction in order to increase the engaging capabilities of the system. In spite of the expressive playfulness, our
While we observed social learning mostly relatively close such as social learning, teaching, discussion and nudging. behavior patterns emerged in relation to the installation, front of the projection, various individual and group participation was possible in a relatively narrow area in interactive public screens. Previous work has discussed individual and social group engagement in front of the interaction area. The queue in front of the coffee shop, for instance, implied a waiting and a gathering situation, where several people were able to contemplate and debate around MyPosition together, without feeling awkward or exposed. Similarly, some people seemed to avoid the interaction area, and rather congregated around columns and other “comfort spaces” out of the camera view.

**Design Implications:** There could be several strategies to support a good balance between playfulness and meaningful participation. On one hand, it should be fairly easy and fast to contribute meaningfully (in our case, submit a vote, which is then reflected in the visualization), while at the same time misuse was relatively restricted. Indeed, there were very few instances, we observed visitors to engage in publicly ‘challenging’ the vote distribution by submitting twice for opposed options in order to e.g. “do a two-fold manipulation of the results”. While we tried to restrict that by only allowing a tracked user to participate once, we could not provide for a more sophisticated solution (such as face detection) due to ethical reasons. Yet, even initially random behavior with MyPosition (observed in only one case) was quickly followed by a loud reflection in terms of the visibility of the opinion, which suggest that the visible persitency of one's contribution, might also lead to a more ‘considered’ behavior.

**Public Character of Voting**
Participating was public in two regards. First, the voting mechanism implied an ‘immediate publicness’: the participants were very visible to a large audience in the deployment space. Second, participants’ images (in the image mode) could be associated with their votes for the time of the deployment (see “The Identifiable Self”). Despite this ‘immediate publicness’, a large percentage of all passers-by (6.1% in color mode) did vote. However, participants often stated that they would prefer a less public setting in the case of more controversial questions, suggesting a less exposed hallway, or a shorter interaction time.

**Design Implications:** One possible concern is that when publicly expressing one’s opinion, people could participate in a more ‘socially appropriate’ way. While we did not observe people stating a different opinion than what they actually submitted (agreeably, we cannot know their true opinion), people with a more controversial opinion may not have voted in the first place.

**Socio-spatial Patterns of Participation**
Previous work has discussed individual and social group engagement in front of, along, and in close vicinity of interactive public screens [23, 27]. We observed participative behavior in a much wider area than the interaction zone of MyPosition (Fig. 7). While direct participation was possible in a relatively narrow area in front of the projection, various individual and group behavior patterns emerged in relation to the installation, such as social learning, teaching, discussion and nudging. While we observed social learning mostly relatively close to the screen, discussions and nudging happened up to very large distances away from it. Those were mostly the spots, where people obtained a good view of the screen, but were relatively far away from the interaction area. While these spatial specifics relate to the “activation spaces” proposed by [10], we observed that for spaces to be advantageous for active participative behaviors, they ought to provide the adequate social setting for a longer encounter with installation. The queue in front of the coffee shop, for instance, implied a waiting and a gathering situation, where several people were able to contemplate and debate around MyPosition together, without feeling awkward or exposed. Similarly, some people seemed to avoid the interaction area, and rather congregated around columns and other “comfort spaces” out of the camera view.

**Design Implications:** Our findings demonstrate that an interactive public display, featuring a collective depiction of individual participative efforts can influence a much larger area than the interaction zone itself. However, it is important to provide spaces for active engagement with the installation, such as social discussion, that possess both proper visibility and social affordances, yet don’t intersect with the interaction area.

**Limitations**
Obtaining the ‘true’ opinion of citizens in a public context is characterized by many pitfalls, and we did not aim at collecting a representative voting result. Rather, we focused on how MyPosition was able to entice civic discussions and reflections on a locally relevant topic. In this sense, our conversion rate of 5% is comparable or better than conversion rates reported by other public display studies [38]. This emphasizes its usefulness for polls that are more playful and situated, however less “representative” in nature. Furthermore, the objective of our field study was high ecological validity, so naturally, using this method we cannot generalize the results to other settings and questions. The university context might have provided a more friendly audience (e.g., more ‘tech-savvy’ people, ‘safer’ environment etc.), than for instance the grocery store investigated in [35].

**CONCLUSION**
Through the design and evaluation of MyPosition, we learned that an interactive public visualization of a local concern can be a means for civic participation and discussion. Apparently the inherent issues of voting in public (e.g. peer pressure, reluctant acceptance of intermediate results) cannot be avoided. In spite of this, increasing the visual identifiability of participants positively impacted the overall enticement of onlookers to engage with the installation and the underlying topic, however lowered the actual turnout. At the same time, the playful nature of the interaction did not seem to deter people from submitting their stated opinion. We observed considerable discussion and nudging among people, in particular beyond the interaction area in front of the screen. In future studies, it would be worthwhile to further investigate the impact of the context, such as the socio-demographic characteristics of the audience, and to study if such systems can be
